

"Burn Therapy With 'Imanin,'" by V. Drobot'ko, Active Member, Academy of Medical Sciences Ukrainian SSR, and M. Ivanova, Candidate of Medical Sciences, Kiev; Moscow, Meditsinskiy Rabotnik, 13 Jan 56

"Imanin," a bactericidal preparation for external use developed by the Institute of Microbiology of the Academy of Sciences Ukrainian SSR, effective primarily against gram-positive bacteria, has been found to be effective in the treatment of serious burns, even in burns covering 60% of the body area, without forming constricting, disfiguring scars. It was found, in tests conducted on more than 200 patients, that on treatment with "Imanin" second- and third-degree burns heal more rapidly than with the use of other preparations.

"Imanin" has been approved for medical use by order of the Ministry of Health USSR and is being manufactured by the Darnitskiy Chemicopharmaceutical Plant. (U)

Иванова, А. В.

TITLE: Electrolytic separation of chromium from chromic acid solutions containing fluoride ion

SOURCE: Ukrainskiy khimicheskiy zhurnal, v. 29, no. 7, 1963, 759-764

TOPIC TAGS: electrolysis, chromium

ABSTRACT: This study presents the results of an investigation concerning the dependence of chromium yield, by an electrolytic separation from a solution containing chromic acid and fluoride ion, upon the current density and a wide temperature range. The yield of chromium was measured by weighing the cathode after a measured period of time. The anodes were prepared by fusing tin with 2% lead and a small amount of metal was added. It was established that, with an increase of current density and the increase of temperature, the critical current density increased with the increase of temperature. The yield of chromium increased with the increase of temperature, the electro-crystallization process of chromium takes place with the formation of a distinct crystalline structure. It must be

Card 1/2

APPROVED FOR: AF3003999

Notes that with the increase of the electrolysis time from 100 to 200 a. hr., the optimum ratio of $(F^-)/(CrO_4^{2-})$ changes from 1.75 to 2.25-2.50 and this results in the decrease of chromium yield and in the lowering of the quality of deposit.

Periodical : Khim. prom., No 7, 423-428 (39-44), Oct-Nov 1954.

Abstract : In investigating the process of mechanical agitation applied to improve contact between a gas and a liquid, (a) obtained equations which make it possible to determine the power required, (b) established a dependence between the energy expended and the amount of gas driven through, (c) formulated rules to be observed in the design of agitators, (d) demonstrated the advantages of agitators of the hollow tube type. TITLE: On the Catalytic Chlorination of
Methylchlorosilanes in the Liquid-Phase
(O zhidkofaznom kataliticheskom khlorirovani
metilkhlorosilanov)

PERIODICAL: Zhurnal Obshchey Khimii, 1958, Vol. 28, Nr 5,
pp. 1336-1338 (USSR)

ABSTRACT: The chlorination of organosilicon compounds in the
presence of azodinitrile of isobutyric acid is not
described in publications. It was therefore of interest
to try this method of chlorination in the synthesis
of chloromethylchlorosilane. It could be expected that
such a chlorination of the methylchlorosilanes had to
take place at the given chain mechanism and had to lead
to the formation of all kinds of substitution products
in the methyl group. It was actually found that in
chlorination on the given conditions (see table), in

Card 1/3

On the Catalytic Chlorination of the
Methylchlorosilanes in the Liquid Phase

79-28-5-51/69

dependence on the mol ratio of the methylchlorosilane and chlorine, the whole range of chlorine derivatives CH_3SiCl_3 , $(\text{CH}_3)_2\text{SiCl}_2$ and $(\text{CH}_3)_3\text{SiCl}$ with the chlorine atoms in the methyl groups can be obtained as is the case in the photochlorination of the methylchlorosilanes. As it must be taken into account that the chlorine of the methyl group of silane increases its further substitution velocity in chlorination, the catalytic liquid-phase chlorination for the purpose of the synthesis of the monochlorine derivatives must take place in such a way that a sufficient amount of the methylchlorosilane which had not entered reaction remains. Thus the reaction liquid-phase chlorination of methylchlorosilanes- CH_3SiCl_3 , $(\text{CH}_3)_2\text{SiCl}_2$ and $(\text{CH}_3)_3\text{SiCl}$ was investigated in the presence of azodinitrile of isobutyric acid and it was found that in this case, dependent on the mol ratio of silane and chlorine, a whole number of chlorine derivatives containing chlorine in the methyl group can be obtained.

TITLE: A four-runner unit for the continuous casting of steel to 200x200 mm square-section ingots

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 12, 1962, 53 - 54, abstract 12V339 ("Sb. tr. Gos. soyuzn. in-t po proektir. agregatov staleliteyn. i prokatn. proizv-va dlya chem. metallurgii", 1962, no. 2, 17- 23)

TEXT: At the open-hearth shop of the Uzbek Metallurgical Plant a continuous four-runner steel-teeming unit is being mounted for the casting of 200x200-mm square section ingots. The unit consists of four vertical type machines arranged in one line; they are combined into one group and mounted in one pit. The machine operates on the principle of the continuous extraction of the ingots from the water-cooled crystallizers, which are moving reciprocatingly along a vertical while liquid-metal is supplied continuously from the intermediate ladles. The level of the teeming platform of the unit is plus 4.3 m and

centers. The change in the luminescence spectra in several phosphors with mixed bases (NaCl-KCl, KCl-KBr, KCl-RbCl, activated with Tl, and NaCl-KCl-Ag) was also investigated. The authors have arrived at the conclusion, on the basis of the obtained results, that the luminescence centers for the investigated systems represent complexes included in the crystal of the base in the form of an adsorption inclusion, with conservation of the intrinsic coordination; the ions of the activator, on the other hand, which are included in the base in the form of a solid substitutional solution, are not responsible for the radiation. Bibliography, 16 titles. T. Ekaina.

TITLE: On the luminescence center in thallium salt solutions

SOURCE: Optika i spektroskopiya; sbornik statey. v. 1: Lyuminesentsiya.
Moscow, Izd-vo AN SSSR, 1963, 156-160

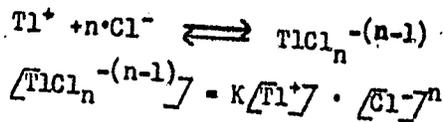

TOPIC TAGS: luminescence center , ionic complex, thallium chloride

ABSTRACT: This analysis is an extension and verification of a work by H. Fromherz (Zs. Phys. 68, 233, 1931), who assumes the structure of active luminescence centers to correspond to ionic complexes in solutions. A detailed study has been made of the inherent luminescence in TlCl solution and of its increase when luminescence centers are transferred into the absorption state. The luminescence intensity from a sample of TlCl is compared to the luminescent radiation of Tl₂SO₄ and TlNO₃ and found to be considerably stronger than both compounds for the same thallium concentration, indicating that Cl ions as well as thallium ions give rise to luminescence. An associative relationship is assumed between Tl ions and Cl ions in the form of a complex

Card 1/2

L 18746-63

ACCESSION NR: AT3002211

and the sign of the complex is determined electrically to be negative. Further analysis shows a luminescence in the violet for undissociated thallium chloride, indicating the presence of electroneutral luminescent centers as well. Maximum TlCl absorption band is quoted to be in the region 225-230 mμ. Orig. art. has: 3 figures and 2 formulas.

TITLE: Luminescence spectra of alkali-halide phosphors with mixed bases

SOURCE: Optika i spektroskopiya; sbornik statey. v. 1: Lyuminestsentsiya. Moscow, Izd-vo AN SSSR, 1963, 167-174

TOPIC TAGS: luminescence, spectra, bases, activators, discrete bands, luminescent centers

ABSTRACT: A detailed investigation was made of the luminescence spectra of alkaline-halide phosphors with mixed bases and 0.01 to 0.1 mol% Tl and Ag activators. The study included a series of bases with both anion and cation components. Base component concentration varied from 5 to 10 mol%. The results are given in the form of three microphotograms for KCl-KBr with various concentrations of Tl, NaCl-KCl, Tl, and NaCl-KCl, and Ag. One such figure is given in Enclosure 1. Analyzing the data in great detail, the authors conclude that the observed changes in the spectra, such as intensity, redistribution between closely

Relation between temperature and concentration quenching in some crystallophosphors. Ya. M. Zelikin, N. I. Izanov, and P. D. Klement (Leningrad State Univ.). *Doklady Akad. Nauk S.S.S.R.* 73, 181-4 (1950).--The max. of the intensity, I , of the green (Cu) emission band (5300 Å.) of ZnS-Cu phosphors, as a function of the Cu content, c , (10^{-4} - 10^{-2} g. g.), in excitation with ~ 3000 Å., moves to lower c with the temp. increasing from 50 to 100-150°. In other words, at a higher temp., concn. quenching sets in at a lower c of the activator. Similarly, with an NH_4NO_3 :Tl phosphor, the optimum concn. of Tl falls from 0.75 to ~ 0.4 mole % between room temp. and 95°. However, ZnS phosphors are known to exhibit complex temp.- and concn.-quenching effects of redistribution of brightness between the emission bands (Levshin, *C.A.* 42, 3296c), and the case of NH_4NO_3 is complicated by the 3 transition points at 32, 84, and 125°. A phosphor free from these objections, BaCl_2 :Cu (0.0031 g mole % Cu), emission max. 4400 Å., showed the shift of the optimum c to lower c with increasing temp. (20, 90, 150, and 220°), in a particularly pure form. For the same phosphor, curves of $\theta = -(1/I)(dI/dT)$ vs. c pass through a max. which lies close to the optimum c . In these 3 phosphors, concn. quenching increases with the temp., whereas temp. quenching is greatest at a concn. of

the activator close to the optimum concn. of activator. However, a phosphor CaI_2 :Pb (0.18 mole % Pb) failed to show a distinct shift of the optimum concn. of activator with temp. (-170 to +80°); in this instance, concn. quenching is on the whole much weaker, and the optimum concn. of activator of ~ 3 mole % is about 10^2 - 10^3 times higher than in the foregoing phosphors. These observations can be fitted into the scheme of Mott's (*Proc. Roy. Soc. A167*, 384 (1938)) formula for the quantum efficiency $\eta = 1/(n + B e^{-U/T})$, if B and U are variable with concn. of activator. It develops that one source of concn. quenching can lie in the increase of temp. quenching with increasing concn. of activator. If, as has been observed, U and B vary with concn. of activator in the same direction, there must exist a concn. at which η will be a max. at a given temp. This can account for the existence of an optimum concn. of activator. In a temp. range where $B e^{-U/T} \gg 1$, $\theta \approx U^2/BT^2$, and if U is a max. at the optimum concn. of activator, θ will pass through a max. at the same point. At the same optimum concn. of activator, other properties of the phosphor (e.g. the elec. cond., or the width of the emission band) can have an extreme value (Nagy, *C.A.* 43, 2515g). A max. of U may be detd. by a change of the form of inclusion of the activator in the host lattice. N. Thon

Title : Peculiarities of Luminescence of Crystal Phosphors with Low Solubility of Activator in Base.

Orig Pub: Optika i spektroskopiya, 1956, 1, No 4, 578-583

Abstract: An investigation is made of the dependence of the intensity I and the spectral composition of luminescence of phosphors on the concentration of the activator A and its solubility in the base. The optimum concentration A in KCl-AgCl and NaCl-AgCl corresponding to the maximum I for shortwave radiation bands ($\lambda_{max} = 275$ and 245 millimicrons) is the same, even though AgCl forms with NaCl a broad region of solid solutions, and is insoluble in KCl. For the long-wave bands, I of NaCl-AgCl increases to 4 molar % A, and in KCl-AgCl it increases to 0.2 molar %. Analogous results are obtained for KCl-TlCl and NaCl-TlCl: the optimum con-

Card : 1/2

USSR / Optics

K

Abs Jour: Referat Zhur-Fizika, 1957, No 4, 10382

centration of $TlCl$, corresponding to the maximum I, is 0.1% molar % for the short-wave bands in both cases, and for the extreme long-wave bands I increases to 10 molar % in $KCl-TlCl$ (yellow band) and to approximately 2 molar % for $NaCl-TlCl$ (azure band). It is concluded that in phosphors with small solubility of its A, optimum concentration (for the long-wave radiation band) is determined by the solubility limits and is not connected with the concentration extension. The undissolved A absorbs a portion of the radiation of the phosphor, and therefore the radiation bands become asymmetrical on the short-wave sides and the maximum shifts towards the longer waves. The appearance of a structure in the spectrum of radiation of $KI-TlI$ and $CsCl-TlCl$ at an excess of A is ascribed to the absorption by the excess TlI or $TlCl$, and not to the splitting of the bands.

TITLE: Effect of the Anion of Activator Salt on Luminescence of Alkali-Haloid Phosphors (Vliyaniye aniona aktivatornoy soli na lyuminesentsiyu shchelochno-galoidnykh fosforov)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1957, Vol 21, #5, p 749 (USSR)

ABSTRACT: The effect of activator salt anions on the luminescence spectra of phosphors based on sodium and potassium haloids activated by silver and thallium haloids was investigated. The following results were obtained:

1. When chlorides (or bromides) of alkali metals are activated by an iodide, a new band arises in the luminescence spectrum. This new band has its own region of excitation. The intensity of this band rises with the increase of iodide concentration in the phosphor.

2. Luminescence spectra of phosphors based on the iodides of alkali metals and activated by chlorides, bromides or iodides of the activator are identical.

(Uzkiye polosy lyuminesentsii fosfora NaBr-CuBr.)PERIODICAL: Optika i Spektroskopiya, 1957, Vol. III, Nr. 4,
pp. 399-400. (USSR)

ABSTRACT: The NaBr-Cu phosphor grown as a monocrystal has two wide luminescence bands: ultraviolet at $365\text{ m}\mu$ and blue at $438\text{ m}\mu$ (Ref. 1). The present authors prepared samples of the NaBr-CuBr phosphor by heating together the base and the activator. The samples were prepared with 0.03, 0.1, 0.3, 1.0 and 3.0 mol.% of CuBr by heating for 10 minutes at $50-350^{\circ}\text{C}$. NaBr was in dehydrated form. In the luminescence spectrum of the samples thus prepared, in addition to the bands present in the monocrystal, there was a new narrow violet band at $421\text{ m}\mu$ (Fig. 1, which shows the spectrum for NaBr-CuBr with 0.5 mol.% of the activator). This new band may be best observed on samples with 1.0 mol.% of CuBr prepared at

Card 1/4

... were obtained using

51-4-23/26

Narrow Luminescence Bands of the NaBr-CuBr Phosphor.

exposures differing by a factor of 10). Luminescence of CuBr occurs only at low temperatures, while that of NaBr-CuBr does not exhibit temperature quenching even at room temperature. Narrow luminescence bands appear also when NaBr is activated with CuCl and CuI. In samples heated to less than 300°C a small shift towards longer wavelengths is observed in these narrow luminescence bands on transition from NaBr-CuCl to NaBr-CuBr and NaBr-CuI. The difference between the spectral positions of the bands of NaBr-CuCl and of NaBr-CuI at -180°C is only 1.5 mμ. On heating to 300°C and higher temperatures, dependence of the spectrum on the anion of the activating salt disappears. The luminescence centres which are responsible for the narrow bands in NaBr-CuBr or CuBr are distributed on the surface of NaBr-CuBr or CuBr. These centres interact weakly with the bulk of the crystal. There are 2 figures, and 4 references, 2 of which are Slavic.

14 Mev cherez sloi delyashchikhya veshchestv)

PERIODICAL: Atomnaya Energiya, 1958, Vol. 4, Nr 4, pp. 337-342 (USSR)

ABSTRACT: If 14 MeV-neutrons pass through thin layers of Th^{232} , U^{233} , U^{235} ,
 U^{238} and Pu^{239} , secondary neutrons are formed. The energy spec-
trum of these neutrons is recorded on photo plates (Ilford G2 and
NIKFI-K). A tritium-zirconium target, which was bombarded
with 150 KeV-deuterons, served as a neutron source.
It was found that the spectra of secondary neutrons, which form
in all isotopes investigated, consist of two components, viz. the
fission neutrons and the spallation neutrons.
Accordingly, the following values were found:

TITLE: Neutron Spectra Forming During the Passage of Neutrons With an Energy of 14 Mev Through Thick Layers of Iron, Lead, and Uranium (Spektry neytronov, obrazuyushchikhsya pri prokhozhenii neytronov s energiyey 14 Mev cherez tol'staye sloi zheleza, svintsa i urana)

PERIODICAL: Atomnaya energiya, 1959, Vol 6, Nr 4, pp 466-468 (USSR)

ABSTRACT: The neutron source is surrounded by the material to be investigated (wall strengths Fe: 5, 10, 15 cm; Pb: 5, 10, 15, 10, 23, 28 cm; U: 5, 10, 20, 31.5 cm). At great distances herefrom the photographic plates Ilford 32 (100 μ emulsion thickness) and NIKFI-K (200 μ emulsion thickness) were placed. The traces of the scattered neutrons are measured and, in consideration of the background neutrons, the actual neutron spectrum is graphically plotted (for the measuring method and the apparatus see references 1 and 2). The effective neutron temperature T_{eff} , which corresponds to the gradient of the curve

$\ln \frac{N(E)}{E}$, amounts to ~ 0.2 to 0.5 Mev within the neutron energy

Card 1/3

SOV/89-6-4-10/27

Neutron Spectra Forming During the Passage of Neutrons With an Energy of 14 Mev Through Thick Layers of Iron, Lead, and Uranium

range ~ 0.5 to 1.5 Mev. It is mainly determined by the neutrons which are only several times inelastically scattered. Within the range of high energy T_{eff} is considerably greater, because here multiple scattering is less. The low-energy-part of the spectrum is not accessible by the photo-plate method and must be obtained by extrapolation. After this has been done, all experimental curves are normalized. The following conclusions may be drawn from these curves: With increasing thickness of the casing the number of high-energy neutrons is reduced and the number of neutrons having an energy of < 1 Mev is increased. In the case of greater thicknesses, T_{eff} decreases and, within the range of 0.5 to 1.5 Mev, it attains 0.3 Mev for iron, 0.5 Mev for lead and 0.2 Mev for uranium. As uranium has a number of low levels, a decrease of neutron energy down to $0.1 - 0.6$ Mev occurs with inelastic scattering, which decrease is not recorded by the photographic plates. The extrapolation carried out is shown by a table. A comparison of experimental curves for materials of equal thickness shows that moderation for lead is lower than for iron and uranium, and that the average neutron energy for lead

Card 2/3

SOV/89-6-4-10/27
Neutron Spectra Forming During the Passage of Neutrons With an Energy of
14 Mev Through Thick Layers of Iron, Lead, and Uranium

is greater than for iron and uranium. This might be explained by the fact that, in scattering, the lead nucleus behaves like a light nucleus, because it has only few levels within the range of 1-4 Mev. The following persons assisted in irradiating plates: Yu. A. Vasil'yev, Ye. I. Sirotinin, N. S. Shvetsov, V. N. Shikin. Microscopic evaluation was carried out mainly by L. S. Andreyeva and N. F. Nikolayeva. Ye. K. Gutnikova also assisted in the work. There are 3 figures, 3 tables, and 6 references, 4 of which are Soviet.

TITLE: Formation of longwave luminescence bands of alkali halide phosphors

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, v. 25, no. 3, 1961, 341 - 343

f

TEXT: This is a reproduction of a lecture delivered at the 9th Conference on Luminescence (Crystal Phosphors), which took place in Kiev from June 20 to 25, 1960. In the literature, opinions differ as to the nature of some luminescence bands of activated alkali halide phosphors (with one activator). Some authors believe that all luminescence bands are caused by energy transitions in one type of luminescence center. Others, however, believe that there are two different types of luminescence centers, one type for the shortwave bands and the other for the longwave ones. The shortwave luminescence bands are typical of small activator concentrations and are ascribed to the activator ions placed in the cation sites of the fundamental lattice. There are various model representations for the cen-

Formation of longwave ...

ters of the respective longwave bands: paired centers; activator ions at the fundamental lattice defects, etc. With a view to clarifying these problems, the authors studied the polarization of luminescence of a larger number of phosphors on the basis of Na and K halides. On the strength of results obtained, they believe that the various bands of a phosphor, and also those of phosphors being almost identical, are produced by centers of a different nature. The study included also the luminescence band of phosphors with a mixed fundamental lattice, and thus, the change of the luminescence spectrum of a pure phosphor to that of another pure phosphor. Here as well, the authors arrived at the conclusion that all luminescence bands of a phosphor belong to different centers, and that the centers themselves represent the type of a molecule of a complex compound of the salt of the basis with the activator. In a discussion following the present lecture, N.N. Kristofel' states that the "dimension" of the centers has a vibrational nature and that one may therefore in a certain sense speak of a quasi-molecule in the crystal. F.D. Klement believes that the above-mentioned results can be explained also on the basis of usual representations, without having to introduce hypothetical "complexes". There are

TEXT: It is reported on the revision carried out by Stal'proyekt in 1960-1961 of specifications of standard injection burners employed in hardening furnaces and other heating units. As a result of the revision all injection burner designs were reduced to 3 standard series II, B and H (P, V, and N). A table of design dimensions of P, V and N-type burners is presented as well as diagrams of their efficiency and rated operational conditions of standard burners. There are 4 figures.
